

Tricolor Serial Communication ASCII Protocol

1.0 Overview.

BG Tricolor series of bargraphs are designed to send and receive formatted strings of ASCII characters via RS-232/485. These message strings contain some combination of the following information: message header, unit id, address of a variable, variable data, length of the variable in bytes, length of the message in bytes, and a checksum. What this provides is flexible a mechanism for users to access information stored in the bargraphs memories. The disadvantage of the system is that PC base application must be programmed with knowledge of variable addresses and their length in bytes. Write messages simply replaces the existing information at the specified location with that in the data field. Read messages simply returns the data at the specified address in Motorola S format.

Variable addresses and lengths can be found in the files variable.c and eeprom.h. Those listed in eeprom.h are stored in non-volatile EEPROM memory and are used for the purpose of configuring the unit.

2.0 Serial Communication Parameters.

The bargraph is configured for the following parameters:

Baud Rate - 9600
Data Bits - 8
Stop Bits - 1
Parity - None

Therefore a typical port configuration for a PC based application would be as follows:

Baud Rate - 9600
Data Bits - 8
Stop Bits - 1
Parity - None
Handshaking - None

3.0 Defining the Message Formats.

3.1 Identifying the Fields.

The formats for reading from a memory location, the bargraph responses, and writing to memory locations are defined in tables 1, 2 and 3.

Tricolor Serial Communication ASCII Protocol

Table 1. Read from Memory Format

Byte Position	ASCII characters	Description
1	'R'	Message Header
2,3	'0'-'9', 'A'-'F'	Unit Id
4,5,6,7	'0'-'9', 'A'-'F'	Variable Address
8,9	'0'-'9', 'A'-'F'	Variable Length: Byte "01", Word "02", Long "04", Float "04"
10,11	'0'-'9', 'A'-'F'	Checksum
12	<CR>	Message terminate

Tricolor Serial Communication ASCII Protocol

Table 2. BarGraph Response Format

Byte Position	ASCII characters	Description
Responses to Byte Reads		
1,2	"S1"	Message Header
3,4	"04"	Byte Count
5,6,7,8	'0'-'9','A'-'F'	Variable Address
9,10,	'0'-'9', 'A'-'F'	Variable Data
11,12	'0'-'9', 'A'-'F'	Checksum
13	<CR>	Message terminate
Responses to Word Reads		
1,2	"S1"	Message Header
3,4	"05"	Byte Count
5,6,7,8	'0'-'9','A'-'F'	Variable Address
9,10	'0'-'9', 'A'-'F'	Variable Data, Most Significant Byte
11,12	'0'-'9', 'A'-'F'	Variable Data , Least Significant Byte
13,14	'0'-'9', 'A'-'F'	Checksum
15	<CR>	Message terminate
Responses to Long and Float Reads		
1,2	"S1"	Message Header
3,4	"07"	Bytes Count
5,6,7,8	'0'-'9','A'-'F'	Variable Address
9,10	'0'-'9', 'A'-'F'	Variable Data, Most Significant Word, Most Significant Byte
11,12	'0'-'9', 'A'-'F'	Variable Data, Most Significant Word, Least Significant Byte
13,14	'0'-'9', 'A'-'F'	Variable Data, Least Significant Word, Most Significant Byte
15,16	'0'-'9', 'A'-'F'	Variable Data, Least Significant Word, Least Significant Byte
17,18	'0'-'9', 'A'-'F'	Checksum
19	<CR>	Message terminate

Tricolor Serial Communication ASCII Protocol

Table 3. Write to Memory Format

Byte Position	ASCII characters	Description
Byte Writes		
1	"W"	Message Header
2,3	'0'-'9','A'-'F'	Unit Id
4,5	"04"	Byte Count
6,7,8,9	'0'-'9','A'-'F'	Variable Address
10,12	'0'-'9', 'A'-'F'	Variable Data
13,14	'0'-'9', 'A'-'F'	Checksum
15	<CR>	Message terminate
Word Writes		
1	"W"	Message Header
2,3	'0'-'9','A'-'F'	Unit Id
4,5	"05"	Byte Count
6,7,8,9	'0'-'9','A'-'F'	Variable Address
10,11	'0'-'9', 'A'-'F'	Variable Data, Most Significant Byte
12,13	'0'-'9', 'A'-'F'	Variable Data , Least Significant Byte
14,15	'0'-'9', 'A'-'F'	Checksum
16	<CR>	Message terminate
Long and Float Writes		
1	"W"	Message Header
2,3	'0'-'9','A'-'F'	Unit Id
4,5	"07"	Bytes Count
6,7,8,9	'0'-'9','A'-'F'	Variable Address
10,11	'0'-'9', 'A'-'F'	Variable Data, Most Significant Word, Most Significant Byte
12,13	'0'-'9', 'A'-'F'	Variable Data, Most Significant Word, Least Significant Byte
14,15	'0'-'9', 'A'-'F'	Variable Data, Least Significant Word, Most Significant Byte
16,17	'0'-'9', 'A'-'F'	Variable Data, Least Significant Word, Least Significant Byte

Tricolor Serial Communication ASCII Protocol

18,19	'0'-'9', 'A'-'F'	Checksum
20	<CR>	Message terminate

3.2 Message Headers.

The ASCII characters 'R', 'W', and 'S' are used to indicate the beginning of read, write, and response messages respectively. Once received by the bargraph, the unit begins storing incoming bytes to the communication buffer. Before responding, the unit will parse the information and determine if the message received is a valid request.

3.3 Unit Id.

The unit id field is used to identify a particular bargraph for which the host device (i.e. PC) would like to communicate. The unit id can be any number from 00 to 99 and must match the unit id of the target bargraph. Each hex digit of the unit id is represented by its corresponding ASCII character.

3.4 Variable Address.

This field corresponds to the address of the variable being accessed. Each character represents the corresponding hex digit of the address location. Table 4. illustrates how the address of variables **Reading** and **NumReading** would be represented.

Table 4. Examples of Address Representation

Variable Name	Address	String Representation
Reading	0x0003	"0003"
NumReading	0x0007	"0007"

3.5 Variable Length.

This field, which is required only for read from memory commands, indicates the size of the variable being accessed. Table 5 contains valid lengths various variable types. When the unit receives a read from memory command, the unit loads into the data field of the response string, the bytes at that make up the variable at the specified location.

Table 5. Examples of Valid Variable Lengths

Tricolor Serial Communication ASCII Protocol

Variable Type	String Length Field
char	"01"
int, unsigned int	"02"
long	"04"
float	"04"

3.6 Byte Count.

This field, which is required only in response and write messages, denotes the number of bytes that make up the address, data, and checksum. Each ASCII character in the byte count, address, data, and checksum fields represent a hex digit. Thus, every 2 characters correspond to 1 byte.

Example 1: Assume the bargraph reading is 5123 and the unit id is "00". The bargraph variable **Reading** is stored as a long variable at memory location 0x0003. Long variables are 4 bytes in length. The command string for retrieving the bargraph reading and the bargraph response is as follows:

Command	"R00000304F8<CR>"
Response	"S <u>107</u> 000300001403DE<CR>"

Underlined is the byte count field. The string "07" corresponds to a hex value of 0x07 and a decimal value of 7. Verified below is that the sum of the address, data, and checksum field indeed total 7 bytes.

	<u>String</u>	<u>Hex Value</u>	<u>Number of Bytes</u>
Address:	"0003"	0x0003	2
Data:	"00001403"	0x00001403	4
Checksum	"DE"	0xDE	<u>1</u>
Byte Count	"07"	0x07	7

3.7 Data.

In response messages, this field contains that data the was requested. The number of bytes in the field is determined by the variable length field in the read form memory command. In write messages, this field contains that data that will be written to the specified memory location. The number of bytes in the field is determined by the type of variable being accessed. Variables of type *char*, *int*, *long* and *float*, will require fields of 1, 2, 4, and 4 bytes in length respectively. Each ASCII character corresponds to a hex digit. Table 6 provides some examples of typical data fields.

Tricolor Serial Communication ASCII Protocol

Table 6. Examples of Data Fields

Variable	No. Bytes	Decimal Value	Hex Value	String	Comments
ADCstatus	1	0	0x00	"00"	Valid Data
ADCstatus	1	1	0x01	"01"	Overrange
ADCavg	2	2500	0x09C4	"09C4"	
ADCavg	2	10000	0x2710	"2710"	
Reading	4	-19999	0xFFFFB1E1 1	"FFFFB1E1"	
Reading	4	-10000	0xFFFFD8F0 0	"FFFFD8F0"	
Reading	4	0	0x00000000	"00000000"	
Reading	4	10000	0x00002710	"00002710"	
Reading	4	99999	0x0001869F	"0001869F"	

3.8 Checksum.

The checksum provides a means of verifying the validity of the transmission. For read from a memory location, the checksum is the last byte of the 1's complement of the sum of the variable address and length. For response and write messages the checksum is the last byte of the 1's complement of the sum of the byte count, address, and data fields.

Example 2: The bargraph variable **Reading** is stored as a long variable at memory location 0x0003. Long variables are 4 bytes in length. Assuming the unit id is 00, the command string for retrieving the bargraph reading is as follows:

Command "R00000304F8<CR>"

The checksum of "F8" was determined in the following manner:

Address	"0003"	0x00	Most significant byte
		0x03	Least significant byte
Length	"04"	<u>0x04</u>	
Sum		0x07	
1's Complement		0xF8	
Checksum string		"F8"	

Tricolor Serial Communication ASCII Protocol

Example 3: Assume the response to the read from memory command in example 2 is:
"S107000300001403DE<CR>"

The checksum of "DE" was determined in the following manner:

Byte count	"07"	0x07	
Address	"0003"	0x00	Most significant byte
		0x03	Least significant byte
Data bytes	"00"	0x00	Most significant word, most significant byte
	"00"	0x00	Most significant word, least significant byte
	"14"	0x14	Least significant word, most significant byte
	"03"	<u>0x03</u>	Least significant word, least significant byte
Sum		0x21	
1's Complement		0xDE	
Checksum string		"DE"	

3.9 String Terminator.

The <CR> character is used to indicate to the bargraph the end of a message.

Tricolor Serial Communication ASCII Protocol

4.0 Read from Memory Examples.

Table 7. Examples of Read from Memory Commands Assuming Unit ID of "00".

Variable Name	Type	Address	Command String	Description
BGmode	int	0x0000	R00000002FD<CR> >	Mode of Operation
EElock	char	0x0002	R00000201FC<CR>	EEPROM lock
Reading	long	0x0003	R00000304F8<CR>	Bar Display Reading
NumReading	long	0x0007	R00000704F4<CR>	Digital Display Reading
Peak	long	0x000B	R00000B04F0<CR>	Peak Value
Valley	long	0x000F	R00000F04EC<CR> >	Valley Value
DecPoint	int	0x0013	R00001302EA<CR>	Decimal Point Location
Alarms	unsigned char	0x0015	R00001501E9<CR>	Status of Alarms
Leds	char	0x0016	R00001601E8<CR>	Trend Leds
ADCstatus	char	0x0017	R00001701E7<CR>	A/D Status
AC_avg	int	0x0018	R00001802E5<CR>	A/D average
CurrentADCavg	int	0x001A	R00001A02E3<CR>	Current A/D average
noZones	int	0x001C	R00001C02E1<CR> >	Number of Zones
Zones[0].start	long	0x001E	R00001E04DD<CR> >	Zone 0 start value
Zones[0].color	char	0x0022	R00002201DC<CR> >	Zone 0 color
Zones[0].segment	int	0x0023	R00002302DA<CR> >	Zone 0 begin segment
BarDpy2	15 char	0x0048	R0000480FA8<CR>	Bar Display Buffer
NumStr2	5 char	0x0057	R00005705A3<CR>	Digital Display Buffer

Tricolor Serial Communication ASCII Protocol

5.0 Write to Memory Example.

Example 4: Assume the bargraph is in standard ASCII mode and it is desired to have the unit display a reading of 5123. Also assume that the unit id is "01". To accomplish this, a value of 5123 needs to be written to the variable **Reading**. Given that this is a long variable stored at memory location 0x0003, the command string would be as follows:

Command "W0107000300001403DE<CR>"

6.0 VARIABLE.C

```
/*
 * File: variable.c

```

7.0 EEPROM.H

```

/*
 * File: eeprom.h
 * Version: 7
 */

/*
 * Revision History
 */

/*
 * 1.0 Initial Isse. RRS.
 * ZF. Added eedata.eebytes.dpydelay. RRS 1/26/96
 * 2. Made ZF option a standard feature. RRS 1/29/96.
 * 3. Added eedata.eebytes.sample_size.
 *    Added eedata.eebytes.signal
 *    Reworked EEPROM structure.
 *    RRS 2/5/96.
 * 4. Changed for readability:
 *
 *         fullscale to digFull
 *         zeroscale to digZero
 *         numfull to barFull
 *         numzero to barZero
 *
 *    RRS 3/28/96
 *
 * 5. Changed the order of the bit fields. RRS 4/18/96.
 * 6. Added RtxZero and RtxFull to eedata.eebytes. These variables
 *    are to be using in conjunction with the AD420 D/A converter
 *    for the new isolated retransmit.
 *    Added calNo to eedata.eebytes. for the purpose of storing a calNo
 *    which can be used for tracking purposes.
 *    RRS 6/17/96.
 * 7. Added variable eedata.eebytes.supervisor2 to allocate space for
 *    future features requiring setup steps.
 *    RRS 7/8/96.
 */

Tricolor Serial Communication ASCII Protocol

8.0 Configuring the Unit Via Serial Communications Port.

Configuring the unit via the serial communications ports involves writing to memory locations in non-volatile EEPROM memory. To provide protection against unintentional writes to configuration parameters, the variable EELock was added. When EELock is cleared, then writes to configurations parameters are allowed. When EELock is set to 1, writes to configuration parameters are inhibited. Thus the configuration sequence is as follows:

1. Clear EELock = 0.
2. Issue write command for configuration parameter.
3. Set EELock = 1.

Table 8 shows several examples of write commands for setting and clearing the EELock variable.

Table 8. Examples of Setting and Clearing EELock.

Operation	Unit Id	Write Command
Setting EELock	00	"W0004000201F8<CR>"
Clearing EELock	00	"W0004000200F9<CR>"
Setting EELock	12	"W1204000201F8<CR>"
Clearing EELock	12	"W1204000200F9<CR>"

8.1 Configuring the Alarms Setpoints.

The unit has available up to 4 alarm setpoints. Associated with each setpoint is a trip value, a type, a mode, and a segment parameter. All but the alarmtbl[.].seg field is programmable. Table 9 indicate the address locations for these fields.

8.1.1 Setting Alarm Trip Values.

The alarm trip value is the reading at which the alarm will engage. A standard, normally open high alarm will close when the reading equals or exceeds the trip value. In contrast, a standard, normally open low alarms will close when the reading equals or falls below the setpoint value. Table 10 provides examples of commands strings for assigning alarm trip values.

Tricolor Serial Communication ASCII Protocol

Table 9. Alarm Addresses

Alarm No.	Field	Address	Type
alarmtbl[0]	trip	0x0E00	long
	type	0x0E04	char
	mode	0x0E05	char
	seg	0x0E06	int
alarmtbl[1]	trip	0x0E08	long
	type	0x0E0C	char
	mode	0x0E0D	char
	seg	0x0E0E	int
alarmtbl[2]	trip	0x0E10	long
	type	0x0E14	char
	mode	0x0E15	char
	seg	0x0E16	int
alarmtbl[3]	trip	0x0E18	long
	seg	0x0E1E	int
	mode	0x0E1D	char
	seg	0x0E1E	int

Table 10. Examples of Alarm Trip Value Assignments

Operation	Address	Command String
Unit 00, Set alarm 0 to 8000	0x0E00	"W00070E0000001F408B<CR>"
Unit 00, Set alarm 1 to 6000	0x0E08	"W00070E08000017705B<CR>"
Unit 00, Set alarm 2 to 4000	0x0E10	"W00070E1000000FA02B<CR>"
Unit 00, Set alarm 3 to 2000	0x0E18	"W00070E18000007D0FB<CR>"
Unit 00, Set alarm 2 to -6000	0x0E10	"W00070E10FFFFE89064<CR>"
Unit 00, Set alarm 3 to -8000	0x0E18	"W00070E18FFFFE0C034<CR>"

Tricolor Serial Communication ASCII Protocol

8.1.2. Setting Alarm Types.

Alarms are classified as either high or low setpoints. As previously mentioned, a high setpoint is an alarm that trips when the reading meets or exceeds the setpoint value. In contrast, the low setpoint trips when the reading meets or falls below the setpoint value. The setpoint type is stored in the variable `alarmtbl[].type`. When `alarmtbl[].type = 1`, then the setpoint is of type high. When `alarmtbl[].type = 0`, then the setpoint is of type low. Table 11 contains several examples of configuring the setpoint type via the serial communication link.

Table 11. Examples of Alarm Type Assignments

Operation	Addresses	Command String
Unit 00, Set alarm 0 to high	0x0E04	"W00040E0401E8<CR>"
Unit 00, Set alarm 1 to high	0x0E0C	"W00040E0C01E0<CR>"
Unit 00, Set alarm 2 to low	0x0E14	"W00040E1400D9<CR>"
Unit 00, Set alarm 3 to low	0x0E1C	"W00040E1C00D1<CR>"

8.1.3. Setting Alarm Mode.

The alarm mode parameter is used in determining how alarms will be tripped. The two modes are standard and failsafe. When the alarm mode is set to standard, they operate as described in section 8.3.2. When the alarm mode is set to failsafe, high setpoints act as lows and low setpoints act as high. Thus a high setpoint in failsafe mode will trip when the reading meets or falls below the setpoint value. Table 12 contains examples of setting alarm modes.

Table 12. Examples of Alarm Mode Assignments

Operation	Address	Command String
Unit 00, Set alarm 0 to standard	0x0E05	"W00040E0501E7<CR>"
Unit 00, Set alarm 1 to standard	0x0E0D	"W00040E0D01E0<CR>"
Unit 00, Set alarm 0 to failsafe	0x0E05	"W00040E0500E8<CR>"
Unit 00, Set alarm 1 to failsafe	0x0E0D	"W00040E0D00E0<CR>"

Tricolor Serial Communication ASCII Protocol

8.1.4. Alarm Segment.

This variable contains segment number corresponding to the setpoint value and is recalculated every time the setpoint value changes. Thus DO NOT WRITE TO THIS VARIABLE !!!

8.2 Setting the Unit Id.

The unit id, which is displayed as a decimal value between 0 and 99 is stored as a binary value in the variable eedata.ebytes.unitid. For example a unit id of 99 is stored as 0x63. Since the unit id is part of the read and write strings, writing to the unit id should occur only when changing the unit id number of a particular bargraph. Table 13 contains examples command strings for changing the unit id.

Table 13. Examples of Unit Id Write Commands

Operation	Write Command String
Change unit 0 to unit 10	"W00040E3A0AA9<CR>"
Change unit 10 to unit 99	"W0A040E3A6350<CR>"
Change unit 99 to unit 15	"W63040E3A0FA4<CR>"
Change unit 15 to unit 1	"W0F040E3A01B2<CR>"
Change unit 1 to unit 0	"W01040E3A00B3<CR>"

Tricolor Serial Communication ASCII Protocol

8.3 Setting the Barform.

The bargraph can be configured for the following five types of barforms: 0%, 50%, 100%, variable, and deviation. The barform parameter is stored in the variable `eedata.eebytes.barform` and can be any value between 0 and 4. Table 14 describes the barforms whereas table 15 contains examples of read and writes to `eedata.eebytes.barform`.

Table 14. Description of Barforms

Barform	<code>eedata.eebytes.barform</code>	Description
0%	0	Bar grows from the bottom segment to the top segment as the reading increases from zeroscale to fullscale.
50%	1	Bar grows from the midscale segment to the top segment as the reading increases from zeroscale to fullscale.
100%	2	Bar grows from the top segment to the bottom segment as the reading increases form zeroscale to fullscale.
Variable	3	Bar grows from the bottom segment to the top segment as the reading increases from the bar zeroscale value to the bar fullscale value.
Deviation	4	Bar grows from the midscale segment to the top segment as the reading increases from the the bar midscale value to the bar fullscale value.

Table 15. Examples of Reading and Writing to the Barform Parameter.

Operation	Command String
Read unit 00 barform	"R000E3B01B5<CR>"
Change barform to 0%	"W00040E3B00B2<CR>"
Change barform to 50%	"W00040E3B01B1<CR>"
Change barform to 100%	"W00040E3B02B0<CR>"
Change barform to Variable	"W00040E3B03AF<CR>"
Change barform to Deviation	"W00040E3B04AE<CR>"

Tricolor Serial Communication ASCII Protocol

8.4 Setting the Decimal Place Location.

The decimal place parameter is stored in the variable `eedata.ebytes.deciplace`. Table 16 defines valid decimal place values. To change the decimal point location, simply write the appropriate value to the address of `eedata.ebytes.deciplace`. Table 17 contains several examples retrieving and changing the decimal point location.

Table 16. Decimal Point Definitions

Description	<code>eedata.ebytes.deciplace</code>
XXXXX.	0
XXXX.X	1
XXX.XX	2
XX.XXX	3
X.XXXX	4
XXXXX	5

Table 17. Examples of Reading and Writing to the Decimal Point Parameter.

Operation	Command String
Read unit 00 decimal place	"R000E3C01B4<CR>"
Change decimal place to XXXXX.	"W00040E3C00B1<CR>"
Change decimal place to XXXX.X	"W00040E3C01B0<CR>"
Change decimal place to XXX.XX	"W00040E3C02AF<CR>"
Change decimal place to XX.XXX	"W00040E3C03AE<CR>"
Change decimal palce to X.XXXX	"W00040E3C04AD<CR>"
Change to no decimal point	"W00040E3C05AC<CR>"
